

Agent writeup

I used Kimi Code CLI throughout this take home! All code is written by Kimi K3 and I sometimes used GPT 5.6 Luna (from opencode) when Kimi was cooking on a big change so I could work in parallel. I spent the ~30 minutes planning the set up and the system design together with just GPT 5.6 Luna and then once I got that to a reasonable point I got Kimi to start coding and you can see the trial with the PRs.

There were a lot of cases of things I had to steer back but this was an obvious one when I started refactoring the frontend after the first pass and it created both an `apps` and `src` folder. I usually review in my IDE and also do a pass in the Github PR diff which is also why I went with PRs instead of direct commits to main.

🔗 wait why do we have `apps` and `src` folder

- Fair catch – that's a real inconsistency I introduced, and it's worth explaining honestly.

Right now you have:

- `frontend/app/` – the Next.js **App Router** directory (routes). This is a Next.js convention; the folder *must* be named `app` for the App Router to work.
- `frontend/src/` – where I put your feature code (`src/features`, `src/lib`, `src/types`).

So there are two "source roots," and that's confusing. The reason they're split is that Next.js supports **two** layouts:

1. `app/` at the project root (what you had originally), with everything else alongside it.
2. `src/app/` – App Router *inside* `src/`, so the whole codebase lives under one `src/` root.

I went with a half-measure: kept `app/` at root and added a sibling `src/` for features. That works (the `@/*` alias points into `src/`), but you're right that it reads as two competing homes for code.

Above is an obvious example but I still like to review my PRs in github before sending them off for review/ merge and I found these 2 which I caught in time
